```
from mlflow.deployments import set_deployments_target

set_deployments_target("databricks")

#This will automatically log all
with mlflow.start_run(run_name="chatbot_rag") as run:
    eval_results = mlflow.evaluate(data = df_qa_with_preds.toPandas(), # evaluation
    data,
                                   model_type="question-answering", # toxicity and
                                   token_count will be evaluated
                                   predictions="preds", # prediction column_name from
                                   eval_df
                                   targets = "targets",
                                   extra_metrics=[answer_correctness_metrics,
                                   professionalism])

eval_results.metrics
```

Figure 7.55 – Running an MLflow experiment with mlflow.evaluate()

Once we've run the experiment, the metrics can be accessed in our notebook and via the UI to easily see how our chatbot is performing in terms of accuracy and professionalism.

Evaluating the chatbot responses

Let's first look at the MLfLow UI in Databricks to compare results between the human-generated and chatbot-generated responses. To do so, navigate to the **Experiments** page and open the experiment matching your notebook name (in this case, `CH7-02-Evaluating Chatbot`). Then navigate to the **Evaluation** tab. We're using this view to see some examples of how closely the bot's answers match what we would expect to see, but it is also very useful when you want to test and compare outputs across different models or chunking strategies.
