Suppose you already have a `highlight` function that takes a name, finds it, and highlights it by invoking `color` and `find` functions that have been implemented elsewhere:

```
highlight = (name) ->
  color find(name), 'yellow'
```

Suppose now that your colleague Bobby Tables wants to use the `highlight` function with multiple names. He changes it to work with an array:

```
highlight = (names) ->
  for name in names
    color find(name), 'yellow'
```

Unfortunately, by changing the function Bobby has broken all the other places in your program where `highlight` is invoked with a single name. Sure, this might be little more than a minor inconvenience, but it's an inconvenience that you can avoid entirely by using some syntactic sugar called *rest parameters*.

The arguments object

Experienced JavaScript developers will be familiar with the `arguments` object and the problems it poses by not inheriting from the array prototype. The good news is that rest parameters in CoffeeScript mean that you *never* have to use the `arguments` object again.
