changes that CoffeeScript introduces to JavaScript. Another one of those changes that you haven't yet explored in detail is called *destructuring*.

7.2. Destructuring

Like spread and rest parameters, destructuring assignment allows you to write with a single, terse expression something that would normally require multiple expressions. Think of rest and spread parameters on steroids—destructuring allows you to unpack *any* array or object into variables or arguments.

7.2.1. Arrays

Suppose your program for the competition table needs to keep track of a particular team (such as your favorite team) by making it the active team. Here's a function that Bobby Tables has already written to switch this active team:

```
makeToggler = (active, inactive) ->
  ->
    temporary = active
    active = inactive
    inactive = temporary
    [active, inactive]

toggler = makeToggler 'komodos', 'raptors'

toggler()
# ['raptors', 'komodos']

toggler()
# ['komodos', 'raptors']
```

Notice how three variables are needed to perform the switch.

That doesn't seem very concise, does it? What's the alternative? With destructuring you can do away with so many expressions by assigning values to multiple variables in a single expression:
