This gets you the same result but without shuffling values around multiple variables. That's a good result because every place you shuffle another variable or create a new bit of state is a place where you might introduce an error. This doesn't just apply to arrays—objects can also be destructured.

7.2.2. Objects

Imagine that you have some data for all of the teams in the competition. All of the data you need is inside an object, but it's not exactly in the structure you want. Here's the current structure:

```
data =
  team2311:
    name: 'Honey Badgers'
    stats:
      scored: 22
      conceded: 22
      points: 11
  team4326:
    name: 'Mongooses'
    stats:
      scored: 14
      conceded: 19
      points: 8
```

Instead of the current structure, how do you get at the specific parts of the data structure that you need? You might pull the object apart manually:

```
for id, team of data
  name = team.name
  points = team.stats.points
  {
    name: name
    points: points
  }

# [ { name: 'Honey Badgers', points: 11 },
#   { name: 'Mongooses', points: 8 } ]
```

That's no fun. With destructuring you can do it succinctly:

```
for id, team of data
  {name: team.name,  points: team.stats.points}
```
