```
});
```

This works in CoffeeScript too:

```
evens = numbers.filter (item) -> item%2 == 0
```

So, if the array methods work in CoffeeScript, should you use them or should you use comprehensions? How do comprehensions compare to these array methods that JavaScript programmers have become more comfortable with? You'll explore that question in this section, learning where comprehensions are appropriate and where they're not.

Careful, the array methods are recent additions

New array methods such as `map` and `filter` are specified in the fifth edition of the ECMAScript specification. Some older web browsers don't support all features of the fifth edition. A compatibility table for ECMAScript 5 features, such as the new array methods, appears in table 13.2.

7.5.1. map

The `map` method is used to take an array and map it to a different array. Suppose you purchase a book for $10, a toaster for $50, and a printer for $200. The tax rate is 10%. If you have these prices in an array, how do you calculate the tax paid on each item? With a comprehension, you do this:

```
paid = [10, 50, 200]
taxes = (price*0.1 for price in paid)
# [1, 5, 20]
```

In JavaScript this is done with the array `map` method (`Array::map`). This technique can be expressed directly in CoffeeScript:

```
taxes = paid.map (item) -> item*0.1
# [1, 5, 20]
```
