A note on generators

Future versions of JavaScript (and by extension CoffeeScript) will include something called *generators* (discussed in chapter 13) that will make comprehensions a more powerful general programming tool. Until that day, though, limit comprehensions to expressing set relationships and use more general-purpose programming constructs, such as functions, elsewhere.

The next piece of syntax used often in JavaScript that needs a discussion in relation to CoffeeScript is the fluent interface. Used by many libraries, including the popular jQuery, the fluent interface is a staple of any JavaScript diet.

7.6. Fluent interfaces

What's a fluent interface? It's a chain of method calls on a single object:

```
scruffy.eat().sleep().wake()
```

It's a bit like a function composition (chapter 6) except that all the function calls act on a particular object. In this section you'll see why fluent interfaces are useful, how to create them, the issues with indentation and side effects, and finally how to create a fluent wrapper for an object that wasn't designed to have one.

7.6.1. Why create them?

Imagine you're helping Scruffy create some animations for an in-browser game called *turt.ly*. He's using an API that Agtron created that allows him to animate the turtle, but he laments that the API is a smidge silly because the class it provides has only four methods: `forward`, `rotate`, `move`, and `swap`:
