```
  @forward size
  @rotate 90
```

The `square` method has made making squares easier. But Scruffy still complains that when he wants to draw two squares he has to keep "saying" *turtle*:

```
turtle = new Turtle
turtle.square 4
turtle.forward 8
turtle.square 4
```

He says this is how his math teacher used to talk to him:

- Scruffy, pay attention.
- Scruffy, stop monkeying around.
- Scruffy, go stand outside.
- Scruffy, go to the principal's office.

How can you avoid sounding like Scruffy's math teacher? In JavaScript you might be tempted to use the `with` statement:

```
turtle = new Turtle();

with(turtle) {
  left();
  forward();
}
```

**This example is JavaScript.**

But the `with` statement hides variable scope and makes your program ambiguous:

**This example is JavaScript.**

```
address = '123 Turtle Beach Road';
with (turtle) {
  rotate(90);
  address = '55 Dolphin Place';
}
```

**Is that the address variable or the address property of the turtle object?**

The `with` statement can make programs confusing. It's been deprecated in JavaScript, and CoffeeScript doesn't have a `with` statement at all. Instead, fluent interfaces provide a solution without the ambiguity. When used with
