Removing parts can make things simpler, but it can also sometimes make them ambiguous. Removing words and symbols from a programming language is no different. To effectively create simple programs, you need to understand where there's potential for ambiguity so that you can avoid it. In CoffeeScript the most common areas where people accidentally create ambiguity are with significant indentation and implicit variable declarations.

7.7.1. Whitespace and indentation

All whitespace looks the same. Lack of visual variety means that you need to take care to make sure programs written in a language with significant indentation aren't ambiguous. You got a hint of this earlier with the turtle:

```
NORTH = 0

turtle
.move
  direction: NORTH
  distance: 10
.stop()
```

When reading this program, it's important to notice that the `move` method is being invoked with an object that has `direction` and `distance` properties. Now consider a `makeTurtle` function that makes and returns an object:

```
makeTurtle = ->
  move: ->
    # move the turtle
    this
  stop: ->
```

Again, when reading the code you need to pay attention. It's not just an object containing a `stop` property that's returned; it's an object with a `stop` property *and* a `move` property. How do you avoid this ambiguity?

Add characters to avoid ambiguity
