

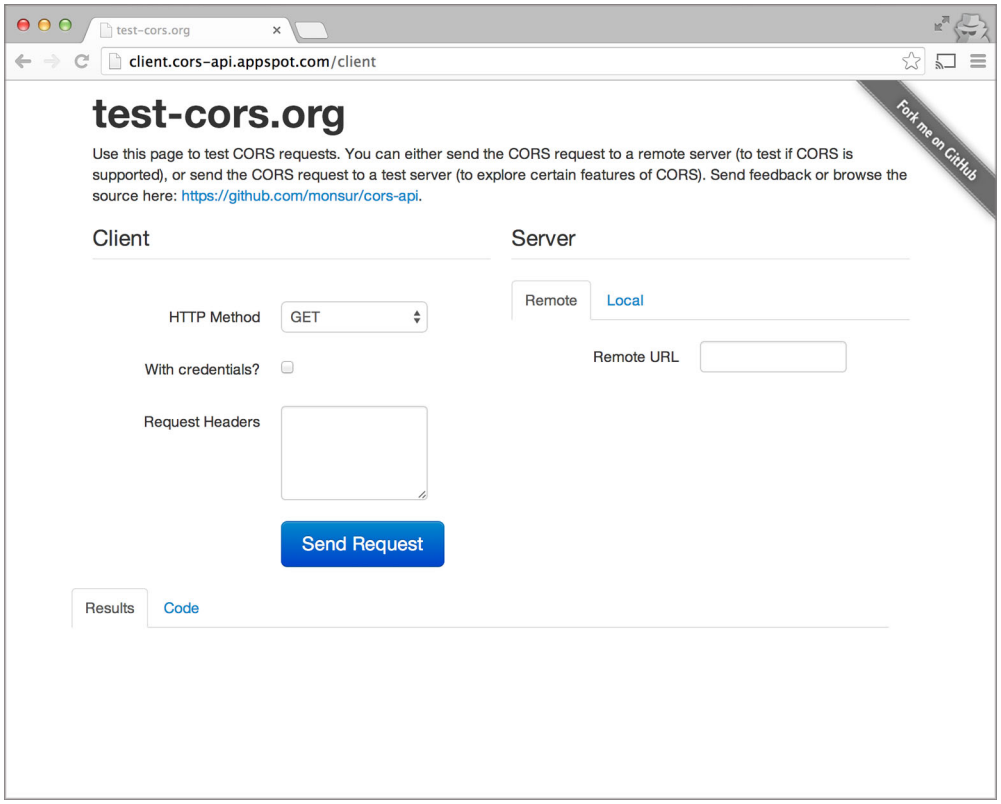

Figure 7.15 The test-cors.org landing page

tab in the response panel (if it's not already selected) and enter http://127.0.0.1:9999/api/posts in the Remote URL textbox.

> **NOTE** You'll also need to whitelist the origin http://client.cors-api.appspot.com in your server app.

If you click the Send Request button, it will send the request to your test server. Figure 7.16 shows an example of what the page should look like.

It may seem odd that the test-cors.org website, which lives on a different server, can access your local server at 127.0.0.1:9999. But remember that test-cors.org makes requests from the browser, so the test-cors.org server itself isn't involved in the request. Since the JavaScript code is running on your computer, it can make requests to localhost.

Another convenient feature of test-cors.org is that you don't need a working CORS implementation to use it. The site also allows requests to be made to its own local server. The next section takes a look at how to do this, and why it's useful.
